Can integrated energy microgrids be distributed optimally based on a consensus algorithm?

Considering the economic benefits of an integrated energy microgrid (IEM), this paper focuses on the distributed optimal dispatch of IEM based on a consensus algorithm. The microgrid structure and multi-agent system are combined organically to get the decentralized architecture of IEM.

Does reinforcement pinning improve distributed generation capacity in microgrids?

Conclusion This study presents a distributed control method based on reinforcement pinning to address the coordination of distributed generation capacity within microgrids. The proposed method effectively minimizes system operating costs and corrects frequency deviations.

Is reinforcement pinning a distributed economic control strategy for microgrids?

Traditional droop control allocates distributed generation (DG) power based on capacity proportion, which leads to high system operating costs. To address this issue, this study proposes a distributed economic control strategy for microgrids based on reinforcement pinning (RP) control.

Does a distributed consensus-based algorithm reduce power generation cost?

The incremental cost rate for devices 1 and 2 is reduced by 21.41%, and 31.43%, respectively. The total incremental cost rate reduction for all three devices, as shown in Figure 8 d, is 14.03%. It can be concluded that the proposed distributed consensus-based algorithm effectively reduces the power generation cost of the whole IEM system.

Is incremental cost rate a consensus variable?

This paper takes the incremental cost rate of each unit in IEM as a consensus variable. Based on the consensus theory, iterative optimization is carried out to achieve the optimal economic operation and power supply-demand balance of IEM. The distributed optimal dispatch is realized, and the convergence of the algorithm is proved.

What does XI mean in microgrids?

The state of node i is denoted by x_i . When all nodes in a network finally attain the same state, it is called consensus, i.e., $x_1 = x_2 = \dots = x_n$. The method of economic operation in microgrids mainly applies first-order discrete consensus algorithms, which are characterized by fast convergence and simple interaction logic.
