

Solar photovoltaic panel characteristic curve

The IV curve of a solar cell is the superposition of the IV curve of the solar cell diode in the dark with the light-generated current.¹ The light has the effect of shifting the IV curve down into the fourth quadrant where power can be extracted from the diode. Illuminating a cell adds to the normal "dark" currents in the diode so that the diode law becomes:

Electrical analysis, such as monitoring the illuminated/dark curve, is one technique for characterizing PV Panel degradation. Electrical characterization of a PV panel is attained by measuring the I-V characteristics of field-aged modules and comparing them to the module's initial measured I-V characteristics before deployment in the field.

Every model of solar panel has unique performance characteristics which can be graphically represented in a chart. The graph is called an "I-V curve", and it refers to the module's output relationship between current (I) and voltage (V) under prevailing conditions of sunlight and temperature. The curve looks like a seated person's leg:
